PRESENTATION SCRIPT

RouteBridge Logistics

Last-mile delivery for Nigeria: every order in one place, every delivery proven.

Presenter: [your name]

Length: about 15 minutes of talk, plus an optional 3-minute live demo and questions

Live demo: https://neche.taile59d7a.ts.net (or the Render address)

Code: github.com/Abigail56/Route-Bridge

How to use this script

- Each slide has two parts: **On the slide** (what the audience sees: keep it short) and **What to say** (read it, or say it in your own words).
- Times are a guide. If you are running late, shorten slides 10 and 12; never skip the problem (2) or the delivery code (7).
- Speak to the room, not the screen. Pause after each slide title for one breath.
- The questions at the end are the ones people ask most. Read them once the night before.

RUN OF SHOW

Timing at a glance

Title

ON THE SLIDE

- RouteBridge Logistics
- Last-mile delivery for Nigeria
- Your name · the date · the live demo link

WHAT TO SAY

> Good morning, everyone. My name is [your name], and this is RouteBridge Logistics.
>
> In one sentence: RouteBridge gets parcels to the right door, with the right cash, and proves it, even when the network is bad.

Move on with: “Let me start with why this matters.”

SLIDE 2 · 1:15

The problem

ON THE SLIDE

- Orders scattered across WhatsApp, Instagram, calls and spreadsheets
- Vague addresses: “opposite the blue church, after the second junction”
- Nobody knows which rider holds which parcel
- A rider can say “delivered” when it was not
- Cash on delivery is reconciled by hand, shop by shop
- Mobile data drops mid-route, so online-only apps fail

WHAT TO SAY

> Same-city delivery in Nigeria runs on calls and trust. A shop takes orders on WhatsApp, writes them in a notebook, and calls a rider.
>
> Addresses are landmarks, not street numbers, so riders get lost and call the customer three times.
>
> Once the parcel leaves, nobody can see where it is. And when a rider says it was delivered, there is no proof, so disputes follow.
>
> Then there is the money. Most customers pay cash on delivery, and shops spend hours every week working out what they are owed.
>
> Finally, the network itself: an app that needs signal all the time simply stops working in the middle of a route.

Move on with: “This is the gap RouteBridge was built to close.”

SLIDE 3 · 0:45

Who we are and our mission

ON THE SLIDE

- RouteBridge Logistics: a Nigerian last-mile delivery company
- Mission: to make every delivery in Nigeria one people can trust
- Values: Trust · Reliability · Fairness

WHAT TO SAY

RouteBridge Logistics is a last-mile delivery company. We pick up parcels from shops and online sellers and bring them to their customers, with cash on delivery collected and settled properly.

Our mission is to make every delivery in Nigeria one people can trust: the shop knows it will arrive, the customer knows when, and everyone knows the money comes back.

We built our own platform to do that, and that platform is what I will show you today.

Move on with: “So what does the platform look like?”

SLIDE 4 · 1:00

The solution: five screens, one system

ON THE SLIDE

- Public website: landing page, plans, sign-up
- Operations console: dispatch board, live map, orders, reconciliation, reports
- Shop portal: place orders, follow them, statements, claims, billing
- Driver app: works offline, installs from a link
- Customer tracking page: no app or sign-in needed

WHAT TO SAY

RouteBridge is one system with five screens, each for a different person.

Visitors see the public website, with what we do, our plans and a sign-up button.

Our own team works in the operations console: they assign riders on the dispatch board, watch the live map and reconcile the cash.

Shops get their own portal, where they place orders and see their statements. A shop only ever sees its own orders.

Riders use a driver app that installs from a link and keeps working without signal.

And customers get a tracking link: no app to install, no account to create.

Tip: Show one screenshot per screen if you have room on the slide.

SLIDE 5 · 1:15

How one delivery flows

ON THE SLIDE

- Shop places order → Admin assigns a driver → driver gets an alert
- On the way → customer watches it live → arrived
- Customer gives the code → proof and cash recorded → statement

WHAT TO SAY

Let me walk you through one delivery.

A shop places an order from its portal: the customer’s name, phone, landmark address and zone.

On the dispatch board, the Admin assigns a driver who covers that zone, or the system does it automatically, choosing a free driver nearby. The driver gets a phone alert.

When the driver sets off, the customer’s tracking page shows the rider on a map, and only while the parcel is on the way.

At the door, the customer gives the driver a one-time code. Only when the server confirms that code does the delivery count as done. The driver records the cash collected.

At the end of the period, the shop gets a statement: cash collected, minus delivery fees, plus any approved claims.

Move on with: “Let me show the features that make this work.”

SLIDE 6 · 1:00

Key features

ON THE SLIDE

- Landmark and zone addressing
- Offline driver app with automatic sync
- Live tracking for customers
- Delivery code, photo and signature as proof
- Cash reconciliation, statements and claims
- Automatic assignment by zone and distance
- Audit log of every important action

WHAT TO SAY

A few features I want to highlight.

Addresses work the Nigerian way: a landmark plus a zone, and each driver only gets jobs in the zones they cover.

The driver app saves every step on the phone and sends it in order when the signal returns, so nothing is lost on a bad road.

Shops can raise a claim for a damaged or missing parcel; our team approves or rejects it with a reason the shop can see.

And every important action is written to an audit log that cannot be edited, so we can always answer “who did what, and when”.

SLIDE 7 · 1:00

The delivery code: proof you can trust

ON THE SLIDE

- “No code, no delivered”
- The customer gets a one-time code; the rider never sees it
- Shown on the customer’s tracking page (and by text when SMS is on)
- Stored hashed, expires, limited attempts
- A photo alone is not accepted as proof

WHAT TO SAY

This is the heart of RouteBridge.

When the rider arrives, the customer receives a one-time delivery code. The rider never sees it: the customer reads it out only when the parcel is in their hands.

The server stores only a scrambled version of the code, it expires, and wrong guesses are limited and recorded. A photo or a signature on its own is not enough.

So “the rider said it was delivered” is no longer an argument. Either the customer confirmed it, or it is not delivered.

Move on with: “Trust also starts with who can sign in, so let me talk about accounts.”

SLIDE 8 · 1:00

Accounts and sign-in

ON THE SLIDE

- Our own sign-in: email and password, or Continue with Google
- Passwords stored as Argon2id hashes, never the password itself
- Sign-up asks name, email, phone, country, state and region
- Sessions in a secure cookie, checked on every request; sign out on every device
- Shops and drivers sign up, then the Admin adds them by their ID

WHAT TO SAY

RouteBridge has its own sign-in. People can use an email and password, or simply Continue with Google.

We never store passwords. We store an Argon2id hash, which is the method security experts recommend today, so even a copy of the database would not reveal anyone’s password.

Sign-up asks for name, phone, country, state and region, so we know who we are working with and where.

After signing up, a shop or a driver gets an ID and sends it to our Admin, who adds them in the right place. Nobody gets access to a company’s data just by signing up.

Sessions end after twelve hours, or after thirty minutes without activity, and anyone can sign out of every device at once.

SLIDE 9 · 1:00

Architecture

ON THE SLIDE

- Browser or phone → Next.js website → FastAPI API
- PostgreSQL (with PostGIS for maps), Redis, MinIO for photos
- Background workers: outbox, notifications, maintenance
- Outside services: Google sign-in, Paystack, SMS, email, push alerts
- Runs in Docker: one command starts everything

WHAT TO SAY

Here is how it fits together.

Everything people see is a Next.js website. It talks to one API built with FastAPI in Python.

Data lives in PostgreSQL, with PostGIS for locations. Redis handles rate limits and the live updates on the dispatch board, and delivery photos go to object storage.

Slow work, like sending notifications, happens in background workers, so the screens stay fast.

The whole system runs in Docker, so it starts the same way on my laptop, on a server or on Render.

SLIDE 10 · 1:00

Technology choices

ON THE SLIDE

- Backend: FastAPI, SQLModel, Alembic, PostgreSQL, Redis, Argon2, PyJWT, pytest
- Frontend: Next.js 14, React, TypeScript, Leaflet maps, service worker + IndexedDB, Vitest
- Why: proven, free, well documented, fast to build with

WHAT TO SAY

A word on the tools. I chose proven, free, well-documented technology.

FastAPI checks every request’s data automatically and documents the API for free. Alembic keeps the database structure versioned, so every server can be upgraded safely.

On the frontend, Next.js and TypeScript catch mistakes before they reach users, and the service worker with IndexedDB is what lets the driver app work offline.

Maps use Leaflet with OpenStreetMap, so there is no map bill while we grow.

SLIDE 11 · 0:45

Security and keeping companies apart

ON THE SLIDE

- Every record belongs to one company; every route checks the role
- Shops only reach their own portal and their own orders
- Bank details kept in a separate table only finance roles can read
- Rate limits on sign-in; signed webhooks; production refuses unsafe settings

WHAT TO SAY

Security is built in, not added on.

Every record belongs to one company, and every request checks who you are and what your role allows. A shop can never see another shop’s orders, or our riders’ details.

Sensitive data like bank details is kept separately and only shown to the people who need it.

And if someone tries to start the system in production with an unsafe setting, it refuses to start and says exactly what is wrong.

SLIDE 12 · 0:45

Reliability

ON THE SLIDE

- Outbox pattern: no lost notifications
- Idempotency: a retried payment or webhook is processed once
- Circuit breakers around outside services
- Backup and restore tested; monitoring with Prometheus and Grafana

WHAT TO SAY

Deliveries cannot depend on luck, so reliability matters.

Every event is saved first and sent afterwards, so a crash never loses a notification. A payment that Paystack reports twice is still counted once.

If an outside service like SMS goes down, RouteBridge keeps working and catches up later.

And backups are not just taken, they are restored and compared table by table, so I know they actually work.

SLIDE 13 · 0:45

Plans and payments

ON THE SLIDE

- Free trial 14 days (30 orders)
- Basic ₦5,000 / month (150 orders)
- Standard ₦15,000 / month (600 orders)
- Pro ₦40,000 / month (3,000 orders)
- Shops pay online with Paystack; deliveries on the road are never stopped

WHAT TO SAY

> This is how RouteBridge earns money.
>
> Every shop starts with a free 14-day trial, then picks a monthly plan: Basic at five thousand naira, Standard at fifteen thousand, or Pro at forty thousand, depending on how many orders they send.
>
> Shops pay online with Paystack from their own portal. If a plan runs out, the shop cannot place new orders until it renews, but parcels already on the road are never touched.
>
> The prices on the website come straight from the system, so what a shop sees is always what it is charged.

SLIDE 14 · 0:45

Testing and quality

ON THE SLIDE

- 272 automated backend tests · 65 frontend tests
- Type checking and linting on every change
- Real screens checked in a browser
- Database built from empty and upgraded in tests

WHAT TO SAY

> I test everything I build.
>
> There are 272 automated backend tests and 65 frontend tests. They cover the rules that matter most: who can see what, delivery codes, payments, and sign-in, including attempts to break in.
>
> Every screen change is also checked in a real browser, because code that compiles is not the same as a page that works.

SLIDE 15 · 0:45

Honest limits and next steps

ON THE SLIDE

- Today: SMS waits for an approved sender ID; no own domain yet; driver app is a web app
- Next: live SMS (Termii), own domain, native Android app, load testing, security review, local languages

WHAT TO SAY

I want to be honest about where the project is today.

Text messages are switched off until our sender ID is approved; for now, customers see their code on the tracking page. We do not have our own domain yet, and the driver app is a web app rather than a store app.

Next, I want to switch on live SMS, move to our own domain, build a native Android app for drivers, test it under heavy load, have it security-reviewed, and add local languages.

SLIDE 16 · 3:00

Live demo (optional)

ON THE SLIDE

- Landing page → Plans
- Sign in with Google
- Platform console → workspace
- Dispatch board and live map
- A tracking page

WHAT TO SAY

Let me show you the real thing.

This is the public website: about us, our mission, how it works, and the live plans.

I sign in with Google. As the administrator I land on the platform console and open our workspace.

This is the dispatch board, where orders wait to be assigned, and this is the live map.

And this is what a customer sees: their parcel’s progress, with no app and no account.

Tip: Rehearse the demo once on the same network. If anything fails, switch to screenshots and keep talking; never debug in front of the audience.

SLIDE 17 · 0:30

Close and questions

ON THE SLIDE

- RouteBridge Logistics: every order in one place, every delivery proven
- Live demo link · code link · your contact

WHAT TO SAY

To close: RouteBridge brings orders, riders, customers and cash into one system, built for Nigerian roads and Nigerian networks, where every delivery is proven by the customer.

Thank you for listening. I am happy to take your questions.

BE READY

Likely questions and short answers

Q. How is this different from just using WhatsApp and a spreadsheet?

WhatsApp cannot tell you where a parcel is, cannot prove the customer received it, and cannot add up cash on delivery. RouteBridge does all three, automatically, with a record nobody can quietly change.

Q. What stops a rider from faking a delivery?

The delivery code. Only the customer has it, the rider never sees it, and the server checks it. Without the right code, the delivery is not marked done; wrong guesses are limited and recorded.

Q. What happens when the rider has no network?

The driver app saves every step on the phone, protected, and sends them in the right order when the signal returns. The rider can keep working.

Q. How do you protect passwords and accounts?

Passwords are stored as Argon2id hashes, never in plain text. Sessions sit in a secure cookie the page’s scripts cannot read, every request is checked, sign-in attempts are rate limited, and people can sign out of every device. Google sign-in is checked against Google’s own keys.

Q. Why did you build your own sign-in instead of using a service?

To avoid a monthly per-user fee, to keep all user data in our own database, and because a sign-in service’s production setup needed a domain we do not have yet. It also let me add Nigerian details such as state and region at sign-up.

Q. Can one shop see another shop’s orders?

No. Every request checks the person’s role and company, and shops can only reach their own portal. This is covered by automated tests.

Q. How do you make money?

Shops pay a monthly plan: Basic ₦5,000, Standard ₦15,000 or Pro ₦40,000, after a 14-day free trial, paid online with Paystack.

Q. Is it ready for real customers?

The core is built and tested. Before a full launch I need live SMS with an approved sender ID, our own domain, and a load test and security review.

Q. What was the hardest part?

Making delivery trustworthy without trusting anyone: the delivery code flow, offline sync for riders, and settling payments exactly once even when the payment provider reports them twice.

Q. What would you do with more time or money?

A native Android app for riders, live SMS and WhatsApp messages, route planning across many stops, and support for local languages.

If you do not know an answer: say “That is a good question. I have not tested that yet, and it is on my list”, then move on. It is better than guessing.
